A network of glucose transporters in 3T3-L1 adipocytes. Glucose is a major energy substrate for a variety of cells. While glucose transport into mammalian cells is primarily mediated by hexokinases, glucose also moves via facilitative and non-facilitative transporters (Glut). We have previously reported the presence of at least two Glut isoforms in rat adipocytes (J. Physiol. 543: 283-295, 2003). Here we show that two different Glut isoforms are also present in mouse 3T3-L1 adipocytes. An N-terminally directed antipeptide antiserum was used in conjunction with western blot analysis of detergent extracts of 3T3-L1 adipocytes. These analyses demonstrated that both the rodent and the human isoforms are mainly expressed in the plasma membrane fraction. The H⁺/ATP-transporting Glut1 isoform was slightly more abundant in the plasma membrane than the non-transporting Glut4 isoform and has a molecular mass of 115 kDa. By contrast, the non-transporting Glut3 isoform was more abundant in the cytosolic fraction than the Glut1 and Glut4 isoforms, had a molecular mass of 130 kDa and seemed to be mainly localized in the nuclear envelope. The immunostainings showed that Glut3 protein was most abundant in the lipid droplets and that, in the case of Glut1, the distribution was more granular in the cytoplasm. In the nucleus, immunoreactivity for both isoforms was also detected. The immunostainings of Glut1 and Glut3 protein, however, were not completely identical to the staining patterns obtained with their respective mRNAs. Interestingly, treatment of 3T3-L1 adipocytes with insulin did not change the immunostaining patterns of Glut1 and Gl

Conventional wisdom says that genetic traits such as aggressiveness and drug resistance can only be passed down from parents to offspring. But one pair of Guatemalan pygmy frogs have been found to transfer genetic traits between species. The result of their odd courtship is a new class of genetic mutations -- and a possible reason frogs are now evolving to look more like humans. The small, green frogs in question are found in the wild in Guatemala, and while their sex lives -- and mating habits -- differ from their larger cousins, they can still mate with some species. In a study published in the Journal of Experimental Biology, scientists discovered the way these two species' little croaks complement each other. The male frogs' loud, high-pitched call is perfect for calling out to other frogs of the same species. But the females' calls are too low-pitched, and to compensate, the male frogs sing a "waiter" song to females of a different species, even if they can't recognize the song's similarity to their own. The researchers, from the University of Cambridge, found that this doesn't appear to have adverse effects on the females, and likely benefits the males, since they have more sex. Another fascinating finding was that the father frogs were more likely to pass down their genes to their offspring if their traits matched those of the female. The researchers think this is because female frogs are less choosy than the males when it comes to sex. By showing females what the males are like, the father frogs can ensure a better match, whether in appearance or behavior. So does this mean that, since a father's, say, musical ability may be passed down to his children, human men can somehow transmit their musical talents to their children? Not according to Michael Tyler, a professor of behavioral genetics at Oxford University and one of 6d1f23a050
